Cable-Based Robotic Crane (CBRC): Design and Implementation of Overhead Traveling Cranes Based on Variable Radius Drums

Lorenzo Scalera, Paolo Gallina, Stefano Seriani, and Alessandro Gasparetto

Abstract—In this paper, we present a new family of overhead traveling cranes based on variable radius drums (VRDs), called cable-based robotic cranes (CBRCs). A VRD is characterized by the variation of the spool radius along its profile. This kind of device is used, in this context, for the development of a cable-robot, which can support and move a load through a planar working area with just two degrees of freedom. First we present the kinematic analysis and the synthesis of the geometry of a VRD profile. Then, the schema of a bidimensional horizontal moving mechanism, based on the VRD theory, and an experimental prototype of a three-dimensional CBRC are presented. The features of this wire-based overhead crane and an analysis of cables tensions are discussed. Finally, the performance of this mechanism is evaluated, demonstrating a deviation between the end-effector and the nominal planar surface of less than 1% throughout the whole working area.

Index Terms—Cable robot, cable-based robotic crane (CBRC), overhead traveling crane, profile synthesis, variable radius drum (VRD).

I. INTRODUCTION

CABLE robots are a special class of manipulators in which flexible cables, rather than rigid links, are used to actuate the end-effector. The main advantages of this class of robot over conventional ones are that cable-based robots can have a larger workspace, they can easily be made to be reconfigurable and modular [1], they are lighter than their rigid-links counterparts, they can be easily transported, and their end-effector can achieve high accelerations and velocities. For these reasons, during recent years, cable-driven systems have received attention and different kind of cable robots have been investigated. Applications of cable robots span from heavy load and large-scale manipulation [2]–[5], building tasks [6], [7], to rescue operations [8] and upper limbs rehabilitation [9], [10]. Cables have also been employed in surgical robots to reduce surgeon fatigue and facilitate supervised telesurgery [11]–[14]. Cable-suspended robots are also used to manoeuvre aerial camera systems (sky-cams or spider-cams) over large areas, such as a stadium [15], [16]. Several cable-suspended parallel robots have been studied and implemented in the recent years. Examples can be found in [17]–[19].

Disadvantages of a cable-based robotic system include redundancy (as cables can carry load in tension but not in compression) and interference between cables and environment. For these reasons, several research works have been conducted over the years, especially for control purposes [20]–[23], dynamic modeling, and trajectory tracking [24].

Since cables are used in power transmissions, drive systems, and load handling, drums and pulleys have been used in different kind of applications. A drum, or spool, consists of a spindle with flanges, around which a cable is wrapped. The cylindrical surface of an ordinary drum has a constant radius [25]. A typical device, in which an ordinary drum is employed, is a winch [26]. It essentially consists of a movable drum around which a cable is wrapped, so that the rotation of the drum produces a drawing force at the end of the cable. Winches are usually equipped with a ratchet wheel and a pawl to prevent slippage of the load [27].

Examples of research studies in cable-drum systems can be found in [28], where a cable mechanism is used as a linear motion sensor, in [29], where a study on the prediction of slip in a cable-drum system is proposed, and in [25], where the transmission backlash of a precise cable drive system is analyzed and experimentally measured.

While traditionally drums and winches are characterized by a constant radius, in this paper, we propose the use of a variable radius drum (VRD), a mechanical device consisting of a drum with a radius that changes along its profile. As the VRD is rotated by an angle $\alpha$, a correspondent length of cable is released or wound. This length can be expressed by a nonlinear function $g = g(\alpha)$, which depends on the VRD profile and on the angular position. With respect to constant radius drums with radius $r$, where the length of the released cable is given by the linear function $g = \alpha r$, in a VRD, it is possible to synthesize a specific profile shape in order to obtain the desired relationship $g = g(\alpha)$. Furthermore, in a VRD, a specific profile shape can be defined in order to modify the value of the torque generated by...
the cable on the VRD itself [30]. The concept of the VRD has been introduced in [31].

This paper presents a new family of overhead traveling cranes based on VRDs. These cable-driven mechanisms are capable of supporting and moving a load on a planar working area, by using just two degrees-of-freedom (DOFs).

Section II briefly summarizes related works that can be found in the literature. Section III gives a general description of a cable-based robotic crane (CBRC). Section IV presents the direct kinematic analysis as well as the synthesis of a VRD, whereas in Section V, a bidimensional horizontal moving mechanism, based on a VRD, is proposed. Section VI reports the inverse kinematic and dynamics of the CBRC, whereas Section VII, an analysis of cable tensions. The experimental prototype of the three-dimensional (3-D) CBRC is presented in Section VIII, whereas in Section IX, the experimental results and the performance of this mechanism are presented. Finally, Section X gives the conclusions of this work.

II. RELATED WORKS

Several examples of the VRD can be found in the literature. Endo et al. proposed a new weight compensation mechanism with a noncircular pulley and a spring [32]. Kilic et al. used a wrapping cams mechanism in the synthesis of nonlinear torsional spring [33], whereas a similar methodology has been used by Schmit and Okada to develop a nonlinear rotational spring [34]. Furthermore, a nonconstant radius pulley for antagonist springs was proposed by Kim and Deshpande [35]. Shin et al. developed a methodology to synthesize variable radius pulleys to improve joint torque capacity in pneumatic artificial muscles, used as actuators for Stanford human-friendly robot [36]. An application of the VRD in locomotion is given by Kljuno et al., who developed RoboCat, a quadruped cable-driven robot [37]. From a kinematic point of view, the synthesis of a VRD was approached by Gallina on a particular case of a rocker-belt mechanism [38].

Concerning traditionally overhead cranes, the main research area is, nowadays, the dynamical modeling and control, in order to eliminate swing effects and ensure system stability. Examples can be found in [4] and [39]–[42].

With respect to traditionally overhead cranes, CBRCs do not require rails or linear guides along the whole span of the system since they are essentially composed of a series of pulleys, drums, and cables. For this reason, their frame is lighter and can be easily disassembled. Furthermore, they are modular and their accuracy only depends on the positioning of the pulleys supports in the set-up phase. Cartesian robots are characterized by a high stiffness and are employed in the handling of small workspaces, where they are extremely accurate for high precision pick-and-place tasks. On the contrary, our device is meant for the handling of large amount of materials in very large workspaces, where the weight of the structure can be a problem. One possible application could be the loading and unloading of materials and supplies for general naval applications, where the workspace is large, the infrastructures have to be light and accuracy is much less demanding. Furthermore, the proposed mechanism could also be deployed as a two-dimensional aerial overhead conveyor for industrial or even mining application, where vertical motion is not required. On the other hand, it has to be noticed that in the cases in which a movement of the load in the vertical direction is needed (such as for pick-and-place tasks), a winch could be mounted on the end-effector of the robotic crane.

To the best of the authors’ knowledge, no examples of overhead traveling cranes based on cables and VRDs can be found in the previous literature.

III. CBRC DESCRIPTION

In this section the description of a CBRC is presented. A graphic representation of this 3-D overhead traveling crane based on VRDs can be seen in Fig. 1.

The experimental prototype is composed of three horizontal moving cable mechanisms (HMCs) identical in size that allow the motion of a load within a planar working area. The two upper mechanisms, identified by VRD 1 and 2, are positioned at the same vertical height in a parallel position. The end-effector of each of these two upper systems is then connected to one edge of the frame of the third mechanism. Thereby, the lower frame, identified by VRD 3, can be moved horizontally through the y-axis. HMC 1 and 2 are connected by means of a transmission shaft, which ensures that they have the same angular position α. The third HMC is located on the lower frame and enables the motion of the load through the z-axis. In this way, the two DOFs CBRC allows the motion of a load through a rectangular working area.

The CBRC prototype is actuated by two motors: the first is directly connected to the upper transmission shaft and ensures the motion through the y-axis, whereas the second, which ensures the actuation along the x-axis, is located on the shifting frame and transmits the motion to VRD 3 by means of two gear wheels.

IV. KINEMATIC ANALYSIS AND SYNTHESIS

In this section, the kinematic analysis of a VRD for each HMMC is briefly summarized. In Fig. 2, a graphical representation of the VRD is reported. On the left, the VRD is constrained
in point $O$ by means of a revolute joint, whereas on the right, an idle pulley is fixed in point $P_0$ with another joint of the same type. The cable is fixed at one end of the VRD in point $F$, it is wound around the drum profile and, initially, it is separated from the VRD in the tangent point $P_t$. We define $A$ as this tangent point fixed at the VRD, at initial conditions, as shown in Fig. 2(a). The cable is then wrapped around the idle pulley and it is tangent to its surface in points $E$ and $C_0$. On the VRD, a marker has been placed in order to easily identify the rotation of the drum with respect to the reference frame, given by angle $\alpha$. We assume $\alpha$ positive in the clockwise direction. In order to introduce the parameters that characterize the kinematic analysis of the VRD, we consider two different configurations of the drum: the case with $\alpha = 0$ and the one with $\alpha > 0$, reported, respectively, in Fig. 2(a) and (b).

1) Case $\alpha = 0$: In this configuration, we assume that the system is in equilibrium. A proper torque acting on the VRD along the counter-clockwise direction is present as well as a force that pulls the cable and balance the torque action. When $\alpha = 0$, we define $l_0$ as the total length of free cable, not wound around the drum, from point $P_0$ to the tangent point $A$. The length of $l_0$ is given by

$$ l_0 = \|AC_0\| + \hat{C}_0E + \|EP_0\|. \tag{1} $$

With the symbol $\hat{}$ we indicate arcs as well as curved segments on the VRD.

2) Case $\alpha > 0$: In this configuration, the drum has rotated in the clockwise direction of an angle $\alpha > 0$. A segment of cable length $\hat{AP}_t$ is wound around the VRD. The length of the segment $PE$ has now changed with respect to the previous configuration: in particular, the length of $PE$ is a function of $\alpha$ and of the shape of the VRD. We obtain

$$ \|P_tC\| + \hat{CE} + \|EP\| = l_0 - \hat{AP}_t. \tag{2} $$

The length of cable wound by the VRD during its rotation is a function of angular position. We define this function $g(\alpha)$

$$ g(\alpha) := \|EP_0\| - \|EP\|. \tag{3} $$

By replacing (1) and (2) into (3), we obtain

$$ g(\alpha) = (\|P_tC\| - \|AC_0\|) + (\hat{CE} - \hat{C}_0E) + \hat{AP}_t. \tag{4} $$

Three addends contribute in (4): the first is the difference between the length of the cable tangent to the VRD and the idle pulley in case $\alpha = 0$ and $\alpha > 0$, the second is the difference between arcs on the idle pulley when $\alpha = 0$ and $\alpha > 0$, the third is the curved profile of the VRD on which the cable is wound.

A. Direct Kinematic Analysis

The direct kinematic analysis aims to calculate the relationship between the function of wound cable $g(\alpha)$ and the angular position of the VRD $\alpha$, by knowing the geometry of the VRD profile. In order to do so, we define $\phi = \phi(\alpha)$ as the angle of the tangent point $P_t$ with respect to the horizontal line and considered positive in the clockwise direction (see Fig. 3). We express the profile of the VRD geometry in polar coordinates, as $\rho = \rho(\beta_r)$. We assume the angle $\beta_r$ positive in the counter-clockwise direction with respect to the frame fixed to the VRD (relative reference frame). Then, the direct kinematic analysis can be developed by solving the integral of the VRD curve:

$$ g(\alpha) = (\|P_tC\| - \|AC_0\|) + (\hat{CE} - \hat{C}_0E) + \int_{-\phi(0)}^{\alpha - \phi(\alpha)} \sqrt{\rho^2 + (d\rho / d\beta_r)^2} d\beta_r. \tag{5} $$

In (5), both the addends $(\|P_tC\| - \|AC_0\|)$ and $(\hat{CE} - \hat{C}_0E)$ are nonlinear functions of the angular position $\alpha$. Their calculation depends on the function $\rho(\beta_r)$ and it has to be analyzed case by case.

Fig. 2. Kinematic analysis of a variable radius drum.

Fig. 3. Variable radius drum parameters in case of point-like idle pulley and neglected cable thickness.
B. Variable Radius Drum Synthesis

In Fig. 3, it can be seen that as the VDR rotates in the clockwise direction, the idle pulley is seen, by an observer on the drum, rotating in the counter-clockwise direction of the same angle. The unit vectors $x$ and $y$ define the reference frame of the VRD, whereas the unit vectors $X$ and $Y$ define the inertial reference frame, with respect to the VRD, fixed to the idle pulley center $P_b$. In this initial approach to the problem, the idle pulley is assumed to be point-like, with a radius equal to zero. In this configuration, we define $c_{ld}$ as the distance between the idle pulley and the center of the VRD, $l_t$ as the distance between tangent point $P_t$ and the idle pulley center, and $\gamma$ as the angle between the segment $OP_t$ and the minimum distance between the cable and the center $O$ of the VRD. The aim of the synthesis is to calculate the profile of the VRD by knowing the wound cable length function $g(\alpha)$.

In local coordinates, the tangent point $P_t$ can be written as a sum of two vectors: the first from $O$ and $P_b$, $\{c_{ld} \ 0\}^T$, the second from $P_t$ and $P_b$, $\{l_t \ 0\}^T$:

$$P_t = T(\alpha)\begin{bmatrix} c_{ld} \\ 0 \end{bmatrix} + T(\alpha)T(-\gamma)T\left(-\frac{\pi}{2}\right)\begin{bmatrix} l_t \\ 0 \end{bmatrix}$$

(6)

where the operator $T(x)$ is the rotation matrix between two reference frames rotated by an angle $x$.

The whole mathematical derivations to obtain the VRD profile synthesis are reported in Appendix A. Finally, the geometry of the VRD profile, in Cartesian coordinates, is given by the following equation (31) in Appendix A:

$$c_{ld}\sin(-\gamma) + \left(1 - \frac{dg}{d\alpha}\right)l_t = 0$$

(7)

where $l_t$ is equal to

$$l_t = \frac{c_{ld}\sin\gamma}{1 + \frac{c_{ld}}{\sqrt{c^2_{ld} - \left(\frac{dg}{d\alpha}\right)^2}}}$$

(8)

and $\gamma$ can be written as

$$\gamma = \cos^{-1}\left(\frac{1}{c_{ld}} \cdot \frac{dg}{d\alpha}\right).$$

(9)

The necessary conditions for the existence of a solution for the VRD synthesis problem are the continuity of $g(\alpha)$ and its derivative. Furthermore, from (8) it has to be noticed that it is necessary that $dg/d\alpha < c_{ld}$. This fact suggests that the idle pulley has to be located at a proper distance from the VRD.

In Appendix B, the VRD synthesis is reported by considering the radius of the idle pulley and the cable thickness.

V. HORIZONTAL MOVING CABLE MECHANISM

Before presenting the prototype of a CBRC, which will be illustrated in Section IV, we propose the schema of a biddimensional HCM based on a VRD, by applying the theory developed in Section II.

An HCM (see Fig. 4), which is a module of the crane, is capable of moving a load along a linear path, parallel to the $x$-axis. This cable-based device can be developed by having recourse just to pulling cables, revolute joints, a regular drum, and a VRD. It has to be noted that no prismatic joints are required.

Conventional planar cable-based robots or mechanisms, which act in a vertical plane and are subjected to gravity force, are, in general, two DOFs systems. The most common configuration of this kind of mechanisms is in the form of a triangle, and a load is suspended through two cables between the related motor drums. The two actuators need to be correctly controlled, if, for example, the load has to be carried through a linear path and a trajectory parallel to the ground has to be followed. Hence, the path planning of such systems acts on a two DOFs system. Here, on the contrary, we present a mechanism able to reach the same target using just one DOF.

The HMC, proposed in Fig. 4, is composed of a VRD, a constant radius pulley (whose radius is $r_1$ and it is represented in grey), two idle pulleys (that revolute around points $P_{b1}$ and $P_{b2}$ and have each one radius equal to $r$), and the load. The latter, represented by a little grey rectangle, is assumed to have mass $m$ at point $L$, where $m$ is the third HCM load for the first two modules whereas the load of the end-effector for the third HCM. The mechanism is located in the vertical plane and, therefore, gravity force is acting on the mass, which is connected by two cables at point $L$. In this context, we assume cable thickness to be null. The left cable goes around the idle pulley, constrained in $P_{b1}$, and it is then wound around the variable radius pulley. On the contrary, the right cable goes around the idle pulley, fixed in $P_{b2}$, and then it is wound around the constant radius pulley. It has to be noticed that the VRD and the CRD are connected to the same shaft and, therefore, they have the same angular position $\alpha$. In Fig. 4, $c_{ld}$ indicates the distance between the centers of the lateral pulleys and the center of the variable and constant radius drums, whereas $d_L$ is the distance between the horizontal linear path of the load and the $x$-axis. Finally, $l_g$ indicates the horizontal distance between point $L$ of the load and the vertical segment intersecting the center of the right idle pulley $P_{b2}$. The angular position $\alpha$ of the VRD is considered positive in the clockwise direction and it is assumed to be null when the load is on the right.
In order to apply the theory developed in Section II, we consider the horizontal moving mechanism in its initial position \((\alpha = 0, I_L = 0)\). In this configuration, the point \(L\) of the load has coordinates \(\{c_d, -d_L\}^T\). When the VRD/CRD rotates in the clockwise direction, a segment of the left cable is wound around the variable radius profile whereas, simultaneously, the right cable is released.

By indicating with \(D_1\) and \(D_2\) the tangency points on the idle pulleys, the synthesis of the VRD profile can be obtained by the following relationship:

\[
g(\alpha) = \overline{D_1(0)D_1(\alpha)} + (||L(0) - D_1(0)|| - ||L(\alpha) - D_1(\alpha)||)
\]

(10)

where

\[
||L(0) - D_1(0)|| = \sqrt{||L(0) - P_b||^2 - r^2} = \sqrt{(2c_d)^2 + d_L^2 - r^2}
\]

and

\[
||L(\alpha) - D_1(\alpha)|| = \sqrt{(2c_d - l_1(\alpha))^2 + d_L^2 - r^2}.
\]

(12)

The function \(l_1(\alpha)\) expresses the correlation between the VRD angular position and the horizontal translation of the load \(L\). It can be written as follows:

\[
l_1(\alpha) = \sqrt{||L(\alpha) - P_b||^2 - d_L^2} = \sqrt{||L(\alpha) - D_2(\alpha)||^2 + r^2 - d_L^2}
\]

(13)

where \(||L(\alpha) - D_2(\alpha)||\) can be expressed as

\[
||L(\alpha) - D_2(\alpha)|| = ||L(0) - D_2(0)|| + r_1 \alpha + \overline{D_2(0)D_2(\alpha)}
\]

(14)

For the sake of simplicity, the arcs \(\overline{D_1(0)D_1(\alpha)}\) as well as \(\overline{D_2(0)D_2(\alpha)}\) can be considered equal to zero in the numeric implementation. Finally, the analytical function for the synthesis of the VRD profile can be obtained by backward replacing (14), (13), (12), and (11) into (10).

The 3-D model of the VRD obtained by implementing the analytical profile in SolidWorks is reported in Fig. 9.

VI. INVERSE KINEMATIC AND DYNAMICS

The inverse kinematic analysis and the reduced inertia of the CBRC are here presented. With reference to Fig. 5, the function \(l_1(\alpha)\) can be expressed as \(l_1(\alpha) = c_d - x\), where \(x\) is the position of the end-effector in the Cartesian space. With simple trigonometric considerations and by knowing that \(LP_{b2} = \sqrt{l_L^2 + d_L^2}\), it is possible to find the values of angles \(\varepsilon_1, \varepsilon_2, \text{and} \varepsilon_3\) as follows:

\[
\varepsilon_1 = \frac{\pi}{2} \frac{r}{LP_{b2}} - \varepsilon_1, \quad \varepsilon_2 = \frac{\pi}{2} - \frac{r}{d_L} - \varepsilon_2, \quad \varepsilon_3 = -\frac{r}{\sqrt{d_L^2 - r^2}} - \varepsilon_3.
\]

(15)

For a given value of the free coordinate \(\alpha\), we can easily calculate the length of an unrolled segment of cable as follows:

\[
\alpha r_1 = ||L(\alpha) - D_2(\alpha)|| + D_2(\alpha)D_2(0) - ||L(0) - D_2(0)||
\]

\[
= \sqrt{l_L^2 + d_L^2 - r^2 + \varepsilon_3 r}.
\]

(16)

The equation of inverse kinematic \(\alpha = \hat{f}(x)\) is straightforward:

\[
\alpha = \frac{1}{r} \left( \sqrt{l_L^2 + d_L^2 - r^2} - \sqrt{d_L^2 - r^2 + \varepsilon_3 r} \right).
\]

(17)

As far as dynamics is conceived, the reduced inertia \(I\) related to the shaft of the VRD can be calculated as follows:

\[
I = I_{VRD} + I_p \tau_{\alpha, \theta_2}^2 + I_p \tau_{\alpha, \theta_1}^2 + m \tau_{\alpha, x}^2
\]

(18)

where \(I_{VRD}\) is the inertia of the VRD, \(I_p\) the inertia of the idle pulley, and \(m\) the mass of the load. Furthermore, we indicate with \(\tau_{\alpha, \theta_2}, \tau_{\alpha, \theta_1}, \text{and} \tau_{\alpha, x}\) the transmission ratios between the VRD shaft (which rotates of an angle \(\alpha\)) and the right pulley (\(\theta_2\), left one (\(\theta_1\)), and the end-effector (\(x\)), respectively. In particular, the contributions of the different transmission ratios can be written as follows:

\[
\tau_{\alpha, \theta_1} = \frac{\dot{\theta}_1}{\dot{\alpha}} = \frac{r_1}{r}, \quad \tau_{\alpha, \theta_2} = \frac{\dot{\theta}_2}{\dot{\alpha}} = \frac{r_1}{r}, \quad \tau_{\alpha, x} = \frac{\dot{x}}{\dot{\alpha}} = \frac{d\hat{f}^{-1}(\alpha)}{d\alpha}
\]

(19)

By considering that

\[
\theta_2 = \frac{r_1}{r} \alpha = \frac{r_1}{r} \hat{f}(x)
\]

(20)
for symmetry, we can easily obtain the expression of $\theta_1$ in function of angle $\alpha$:

$$\theta_1 = -\frac{r_1}{r} f(-x) = -\frac{r_1}{r} f(-f^{-1}(\alpha))$$

(21)

where the direct kinematic equation $x = f^{-1}(\alpha)$ has been taken into account.

Finally, by calculating the derivative function with respect to $\alpha$, the expression of the transmission ratio between the VRD and the idle pulley 1 is obtained:

$$\tau_{\alpha,\theta_1} = \frac{\dot{\theta}_1}{\dot{\alpha}} = \frac{r_1}{r} f'(-x) f'(-f^{-1}(\alpha))$$

(22)

VII. CABLE TENSION ANALYSIS

In this section, we present an analysis of tensions in the cables of the CBRC. For the sake of simplicity, we consider the bidimensional horizontal moving mechanism presented in Section III. In Fig. 6, a graphical representation of cable tensions $T_1$ and $T_2$ in the robotic crane is shown. $L$ is the weight force, whereas $\theta_1$ and $\theta_2$ are the angles between the cables and the vertical plane. It has to be noticed that, in this analysis, the idle pulleys as well as the VRD and the CRD are considered to be point-like.

By solving the horizontal and vertical equilibrium equations system, the two tensions can be easily obtained:

$$T_2 = \frac{L}{\sin(\theta_2) \cos(\theta_1) + \cos(\theta_2)}$$

$$T_1 = T_2 \frac{\sin(\theta_2)}{\sin(\theta_1)}$$

(23)

In order to make the examination nondependent from distance $d_L$ and from interaxle spacing $c_d$, we introduce the parameter $d$, defined as $d := d_L/2 c_d$. Furthermore, the tensions $T_1$ and $T_2$ are divided by the weight force $mg$, whereas the $x$-coordinate by the distance $2 c_d$.

In Fig. 7, the trend of tension $T_1$ over the $x$-axis, for different values of parameter $d$, is reported. It has to be noticed that only tension $T_1$ has been reported, since the two tensions are symmetric with respect to the central vertical axis of the mechanism, corresponding to a value of $x = 0.5$.

In Fig. 8, the maximum tension $T_1$ and its position on the $x$-axis with respect to parameter $d$ are reported. As it can be seen, for $d = 0.3$, a discontinuity point in the position of the $x$-coordinate is present and, for values of $d$ greater than this value, the maximum tension in the cable is equal to the weight force. This examination can be useful in the first stage of the design of a CBRC, when the vertical distance of the end-effector with respect to the pulleys horizontal height has to be chosen. Additionally, it has to be noticed that the torque required to maintain the load in an equilibrium point is null. This is because the potential energy is constant since the load moves along a horizontal path.

VIII. PROTOTYPE OF THE CABLE-BASED ROBOTIC CRANE

A general overview of the experimental prototype is reported in Fig. 9. Before describing the features of the experimental prototype, it is necessary to underline that the fabrication of a VRD is a critical aspect, since its shape cannot be easily obtained by means of traditional manufacturing processes. In order to obtain a working prototype, we have used 3-D printing fused deposition modeling technology, which allows the creation of free-form shapes by means of a 3-D modeling software. Not only the VRDs, but also the CRDs, the idle pulleys,
planar, but they are in the form of a helical cone and a cylinder, respectively. Except when the spiral angle is less than 360°, purely planar VRDs and CRDs are impossible to build. This fact introduces an error with respect to the mathematical theory developed in Sections III and IV, which is inherent to purely planar mechanisms. As it can be seen in Fig. 9, the idle pulleys and the drums are not coplanar. In fact, as the bearings supports (printed in green plastic) for both idle pulleys and drums shafts are mounted on the same plane, a small offset between the tangent point of the cable on the drums and the tangent point of the cable on the pulleys is present. This deviation produces an error source with respect to the nominal behavior of the mechanism but, for the sake of simplicity, it has been neglected in this context.

Finally, the most important error sources that affect the CBRC can be summarized in the following list.

1) manufacturing errors;
2) mathematical approximation in the VRD synthesis [see (14), namely, \( D_1(0)D_1(\alpha) \approx 0 \) as well as \( D_2(0)D_2(\alpha) \approx 0 \);
3) nonplanarity of the idle pulleys and drums;
4) geometrical errors;
5) misalignment of the pulleys and drums axis;
6) cables elongation and elasticity [4], [12], [43].

Cables elongation \( \Delta x \) with respect to the nominal length \( x_0 \) can be calculated with the following equation:

\[
\Delta x = \frac{T(x)}{AE} x_0
\]  

where \( T(x) \) is the cable tension, \( A \) is the cross-sectional area of the cable, whereas \( E \) is Young’s modulus. In the plastic cable employed in our prototype, \( EA \approx 13 \, kN \).

In particular, with respect to Fig. 6, the accuracy errors \( \Lambda_x \) and \( \Lambda_y \) in the \( x \)- and \( y \)-directions, due the cable elasticity and relative to the payload, can be evaluated as follows:

\[
\Lambda_x = \frac{|x_E - x_L|}{mg}, \quad \Lambda_y = \frac{|y_E - y_L|}{mg}
\]  

where \( (x_L, y_L) \) and \( (x_E, y_E) \) are the end-effector coordinates in nominal position and the ones affected by cable elongations, calculated with (23) and (24). Fig. 10 reports the trend of these errors along the \( x \)-axis.

7) scale errors.

The scale error \( e_x \) for a single HMC (see Fig. 6) affects the measure on the end-effector position along the \( x \)-axis, resulting in the following error:

\[
e_x = \frac{(K_1^2 - 1)l_1^2(\alpha) - (K_2^2 - 1)l_2^2(\alpha)}{2L^2}
\]  

where \( K_1 \) and \( K_2 \) are the scale factors on idle pulleys 1 and 2, respectively, \( l_1(\alpha) \) and \( l_2(\alpha) \) are the length of the free-cables 1 and 2 in function of the free-coordinate \( \alpha \), and \( L = 2c_d \).

IX. EXPERIMENTAL RESULTS

The performance of the CBRC here presented can be evaluated by measuring the deviation of the end-effector from a
nominal planar surface. In order to do so, a grid has been marked out on the working area of the overhead traveling crane and the height of the load has been measured, under static conditions, by means of a vertical calliper through the surface in both the $x$- and $y$-directions. On the working area, a sampling interval has been chosen of $\Delta x = 50$ mm and $\Delta y = 50$ mm starting from $(x = 0, y = 0)$ till $(x = 700$ mm, $y = 700$ mm).

In Fig. 12, the experimental results are shown. The red dots indicate the measure points, whereas the blue planar surface is the nominal plane. As it can be seen, the maximum deviation from the theoretic path is actually really small and equal to 5.8 mm. At this value, it corresponds a maximum relative error of 0.83% to the total length of the path in one direction (700 mm). It can be appreciable how the relative error is very small and lower than 1% throughout the whole working area. These results show that the experimental prototype, even in this early stages of development, can achieve its task with acceptable accuracy and precision. Moreover, the offset of the drums does not produce a worrying effect on the performance of the global mechanism. The deviation error could be further reduced by using more accurate manufacturing technologies for the VRD and the pulleys, with respect to 3-D printing technique, e.g., milling machine manufacturing.

Furthermore, the errors along the $x$- and $y$-axis have been evaluated in order to provide the positional accuracy of the upper and lower HMCMs separately. In particular, errors in the $x$-direction have been evaluated by fixing the upper HMCMs and moving only the lower HMCM. In the same manner, $y$ errors refer to the center of the frame of the lower HMCM, when only the two upper mechanisms are activated. As we have done for the evaluation of vertical accuracy, measures in the $x$- and...
In this paper, a new family of overhead traveling cranes, based on variable drums and named CBRC, was presented. The direct kinematic analysis and the synthesis of the geometry of a VRD were proposed. The VRD theory was applied first on a bidimensional horizontal moving mechanism and then to a 3-D overhead crane. An experimental prototype of a CBRC, produced using 3-D printing technology, was presented and an analysis of tensions in cables was provided. Finally, the performance of this mechanism was evaluated, and a deviation of the end-effector from the nominal position of less than 1%, throughout the whole working area in the $x$-, $y$-, and $z$-directions, was found. Furthermore, the cable tensions have been measured and compared with the theoretical values.

The presented prototype of the CBRC highlights the advantages of using VRDs with respect to traditional CDRs, the first and foremost being the simplicity in the required actuation system. In fact, it is well known that one would need several CRDs with a coupled actuation system to drive them in a synchronous manner in order to make the end-effector moving along a linear path on a planar surface. On the other hand, the VRD requires only to compensate the variation of the radius, in order to produce a demanded speed or torque output. Moreover, the CBRC here described is characterized by a lighter weight with respect to traditional overhead traveling cranes, it is reconfigurable and modular. It has to be noticed that in this preliminary prototype, oscillation and vibration effects might occur during the end-effector motion. Even if this problem raises also in traditional overhead traveling cranes, in the presented experimental system, the cables flexibility as well as the pendulum phenomena might introduce negative issues during the movement of the load. From a practical perspective, where stiffness might be required by several applications, this aspect needs to be further investigated, e.g., by implementing antiswing as well as vibration-suppression control strategies [23]. Furthermore, the maximum speed of the system depends on the size of the cables and their tensions, as well as its acceleration is limited by the cables stability, since they support traction but no compression. Such problems have been addressed in other cable robots, where gravity forces are involved [44].

This research study has reached remarkable results in the application of VRDs to cable-based overhead cranes. Nevertheless, improvements can be done in the manufacturing of the complex shapes of VRDs profiles. Furthermore, a complete sensitivity analysis of CBRC kinematics would be useful to evaluate potential issues before providing interesting real applications. In the future, we plan to further investigate cable-driven cranes based on VRDs. In particular, the safety of the system in the case of cable failure [45] can be analyzed and the elongation of the cables [12] can be taken into account.

**APPENDIX A**

**MATHEMATICAL DERIVATIONS OF THE VRD SYNTHESIS**

In this appendix, the mathematical derivations of the VRD profile synthesis are reported.
For the further calculations, it is to be noticed that
\[
\frac{dT(x)}{dx} = T \left( x + \frac{\pi}{2} \right).
\] (27)

In particular, by differentiating (6) with respect to angle \( \alpha \), we can obtain
\[
\frac{dP_t}{d\alpha} = \frac{dT(\alpha)}{d\alpha} \left\{ c_d \ 0 \right\} + \frac{dT(\alpha)}{d\alpha} T(-\gamma) T \left( -\frac{\pi}{2} \right) \left\{ l_t \ 0 \right\} \\
- \frac{d\gamma}{d\alpha} \left( \frac{dT(-\gamma)}{d\alpha} T(\alpha) T \left( -\frac{\pi}{2} \right) \left\{ l_t \ 0 \right\} \\
= T \left( \alpha + \frac{\pi}{2} \right) \left\{ c_d \ 0 \right\} + T(\alpha) T(-\gamma) \left( 1 - \frac{d\gamma}{d\alpha} \right) \left\{ l_t \ 0 \right\}.
\] (28)

The unit vector normal to the VRD profile in tangent point \( P_t \) is
\[
n = T(\alpha) T(-\gamma) \left\{ \frac{1}{\sqrt{\gamma^2 + l_t^2}} \ 0 \right\}.
\] (29)

Since \( dP_t/d\alpha \) points at any time along the tangent line \( P_tP_t \), it is normal to unit vector \( n \). This orthogonality relationship can be written as
\[
n^T dP_t = 0.
\] (30)

By substituting (28) and (29) into (30) and by using the property of orthogonal matrices \( T^T T = I \), it follows
\[
\left\{ 1 \ 0 \right\} T^T (-\gamma) T \left( \frac{d\gamma}{d\alpha} \right) \left\{ c_d \ 0 \right\} \left( 1 - \frac{d\gamma}{d\alpha} \right) l_t = 0
\]
and
\[
c_d \sin(-\gamma) + \left( 1 - \frac{d\gamma}{d\alpha} \right) l_t = 0.
\] (31)

The relationship between the lever arm \( l_o \), the unrolled cable length, and the VRD rotation angle \( \alpha \) is \( l_o = dg/d\alpha \). In particular, from Fig. 3, it can be easily seen that \( c_d \cos(\gamma) = l_o \). By combining the two previous equations, we obtain \( c_d \cos(\gamma) = dg/d\alpha \). At this stage, we can differentiate the previous relationship and, by considering that \( c_d \sin(\gamma) = \sqrt{c_d^2 + l_o^2} \), we obtain
\[
\frac{d\gamma}{d\alpha} = \frac{d\gamma}{d\alpha} \left( \sqrt{c_d^2 + l_o^2} \right).
\] (32)

**APPENDIX B**

**VRD SYNTHESIS BY CONSIDERING THE RADIUS OF THE IDLE PULLEY AND THE CABLE THICKNESS**

In the following, we introduce the radius \( r \) of the idle pulley and the thickness of the cable \( 2f \). The radius \( r \) includes the radius of the idle pulley and half of the cable thickness. In Fig. 16, a graphical representation of this configuration is reported. Similarly to what is stated in (6), the geometry of the VRD can be now expressed as
\[
P_t = T(\alpha) \left\{ c_d \ 0 \right\} + T(\alpha) T(-\gamma) T \left( -\frac{\pi}{2} \right) \left\{ l_t \ 0 \right\} + \chi(\alpha)
\] (33)

where the function \( \chi(\alpha) \) is equal to
\[
\chi(\alpha) = T(\alpha - \gamma) \left\{ \frac{r}{0} \right\} - T(\gamma + \alpha) \left\{ \frac{f}{0} \right\}.
\] (34)

We can express the vector tangent to the profile in \( P_t \) as
\[
dP_t = \frac{dT(\alpha)}{d\alpha} \left\{ c_d \ 0 \right\} + \frac{dT(\alpha)}{d\alpha} T(-\gamma) T \left( -\frac{\pi}{2} \right) \left\{ l_t \ 0 \right\} \\
- \frac{d\gamma}{d\alpha} dT(-\gamma) T(\alpha) T \left( -\frac{\pi}{2} \right) \left\{ l_t \ 0 \right\} + \frac{d\chi(\alpha)}{d\alpha} \left\{ c_d \ 0 \right\} + T(\alpha) T(-\gamma) \left( 1 - \frac{d\gamma}{d\alpha} \right) \left\{ l_t \ 0 \right\} \\
+ \frac{d\chi(\alpha)}{d\alpha} dT(-\gamma) T(\alpha) T \left( -\frac{\pi}{2} \right) \left\{ l_t \ 0 \right\}.
\] (35)

since
\[
\frac{d\chi(\alpha)}{d\alpha} = \frac{dT(\alpha - \gamma)}{d\alpha} \left( 1 - \frac{d\gamma}{d\alpha} \right) \left\{ r \ 0 \right\} \\
- \frac{dT(\alpha - \gamma)}{d\alpha} \left( 1 - \frac{d\gamma}{d\alpha} \right) \left\{ f \ 0 \right\} \\
= T \left( \alpha - \gamma + \frac{\pi}{2} \right) \left( 1 - \frac{d\gamma}{d\alpha} \right) \left\{ r \ 0 \right\} \\
+ \frac{d\chi(\alpha)}{d\alpha} \left\{ c_d \ 0 \right\} + T \left( \alpha - \gamma + \frac{\pi}{2} \right) \left( 1 - \frac{d\gamma}{d\alpha} \right) \left\{ l_t \ 0 \right\}.
\] (36)

It has to be noticed that (35) is equal to (28). Consequently, the orthogonality condition of (30) leads to the same results of (8) and (9). In fact
\[
n^T \frac{d\chi(\alpha)}{d\alpha} = 0.
\] (37)

Finally, we obtain that the geometry of the VRD profile, in Cartesian coordinates, is given by (33), associated with (8), (9), and (34).

**ACKNOWLEDGMENT**

The authors would like to thank Mr. F. Bacciocchini for his help in setting up the system.
