General remarks

Spruce organosolv lignin was received from the Lignocellulosic Biorefinery Pilot Plant, Fraunhofer CBP in Leuna, Germany. The received batch showed an average molar mass of M_n of 0.5 kg/mol and M_w of 5.89 kg/mol, lignin content of 97.1 %, 0.5 % carbohydrates, and 0.2 % ash as described earlier.¹ CHN analysis gave C: 66.79 %, H: 5.84 %, and N: 0.16 %. The OH-group characterization is summarized in Table S1.

All HPLC-grade solvents were used without further purification as obtained from the supplier (Honeywell, VWR, Merck, Sigma Aldrich). Distilled water was produced with an Aquatron AS4 (Bibby). All reagents were commercially available and used without further purification as obtained from the supplier. All oxidized active carbon species (oAC) were synthesized in our lab. Oxidized carbon nanotubes (oCNT) were prepared by HNO₃ oxidation.²

Table S1. Amount of different OH groups (mmol/g of lignin) in spruce organosolv lignin determined by ³¹P NMR analysis.¹

Aliphatic	S + Gcond.	Gnc + H	Total Ph-OH	Total OH	СООН
1.91	1.33	1.98	3.51	5.42	0.18

S+Gcond.: syringyl + condensed guaiacyl; Gnc: non-condensed guaiacyl; H: *p*-hydroxyphenyl; COOH: carboxylic acid; Ph-OH: Gcond. + Gnc + H; Total OH: phenolic OH + aliphatic OH

Carbon material XPS measurements

The X-ray Photoelectron Spectroscopy (XPS) analysis was performed by Thermo Fisher Scientific ESCALAB 250Xi XPS System at the Center of Microscopy and Nanotechnology, University of Oulu (Finland). The monochromatic AlK α radiation (1486.7 eV) operated at 20 mA and 15 kV. The powder samples were put in gold sample holder and O, C, N and Au were measured for all samples. The measurement data were analyzed by Avantage V5 program developed by Thermo Fisher Scientific. Charge compensation was used to determine the presented spectra and the binding energies (BE) were calibrated by the C1s peak position of 284.8 eV. The deconvolution of the peaks was carried out for C1s and O1s with Avantage program utilizing peak BE values for groups as reported for carbon materials by Figueiredo and Pereira.³

Temperature programmed desorption

Temperature-programmed desorption (TPD) of ammonia was conducted in a home-made flow apparatus using a mass spectrometer Hiden HPR20 as analyzer. In a typical TPD experiment, about 0.15 g of the sample was loaded in U-shaped quartz microreactor. To remove weakly adsorbed species, the sample was subjected to a cleaning treatment in Ar flow (50 mL min⁻¹) at 300 °C for 30 min. Afterwards, the sample was cooled at 110 °C under the inert gas flow. Saturation of the samples were performed at 110 °C for 60 min by flowing NH₃ (10%)/Ar (50 mL min⁻¹) or pure CO₂ (30 mL min⁻¹). After saturation, the sample was flushed in Ar flow at 110 °C for 1h to remove physically adsorbed molecules. The TPD profile for each sample was recorded by increasing the temperature with a heating rate of 10 °C min⁻¹ under flow of Ar (50 mL min⁻¹). The desorbed products were analyzed by means of a mass spectrometer operating in the electron impact mode with an ionization energy of 35 eV. The desorbed species were identified on the basis of the intensity of various mass fragments. In particular, the most interesting signal to follow was m/z = 17 for ammonia, m/z = 28 for CO and m/z = 44 for CO₂.

Electrochemical measurements

Indole substrates cyclic voltammetries

Electrochemical tests were performed at room temperature using an Interface 1000 electrochemical workstation (Gamry Instruments). The set-up cell used for the experiments was a three-electrode system consisting of a platinum coil as the counter electrode, a Pt wire as pseudo-reference electrode with Fc/Fc^+ as an internal standard and a glassy carbon electrode as a working electrode. Oxidation potentials were estimated from the irreversible oxidation curves as $E^{p/2}$ which, according to literature, is the value closest to $E_{1/2}$ at the scan rate of 0.5 V/s.⁴

Figure S15. CV of differently substituted indoles in presence of ferrocene as internal standard using a glassy carbon electrode in a $0.10 \text{ M NBu}_4\text{PF}_6$ solution in acetonitrile under Ar. Scan rate: 0.5 V s⁻¹.

Carbon materials cyclic voltammetries

The catalyst ink was prepared by dispersing the powder into a water:isopropanol:Nafion mixture (5 mg catalyst, 20 μ l di Nafion, 500 μ l di water, 500 μ L isopropanol), and then drop-casted onto a Toray paper. The electrochemical measurements were carried out at room temperature by using an Autolab potentiostat/galvanostat (Model 302N) and a RDE (Autolab), both equipped with a three-electrode cell under a stream of purified Ar gas. All potentials were measured with respect to Ag/AgCl electrode contained in a glass tube filled with the supporting electrolyte solution, separated from the solution by a Vycor frit and located close to the tip of the working electrode to minimize the ohmic drop. The counter electrode was a Pt wire directly dipped in the solution. The supporting electrolyte was composed of 0.5 M H₂SO₄ aqueous solution and the scan rate for the CV measurements was of 50 V sec⁻¹.

Examples of NMR spectra of reaction crude mixture for NMR yield calculation with internal standard (trimethoxybenzene)
