Measurement of top quark polarisation in $t$-channel single top quark production

The CMS collaboration

E-mail: cms-publication-committee-chair@cern.ch

ABSTRACT: A first measurement of the top quark spin asymmetry, sensitive to the top quark polarisation, in $t$-channel single top quark production is presented. It is based on a sample of pp collisions at a centre-of-mass energy of 8 TeV corresponding to an integrated luminosity of 19.7 fb$^{-1}$. A high-purity sample of $t$-channel single top quark events with an isolated muon is selected. Signal and background components are estimated using a fit to data. A differential cross section measurement, corrected for detector effects, of an angular observable sensitive to the top quark polarisation is performed. The differential distribution is used to extract a top quark spin asymmetry of $0.26 \pm 0.03\text{(stat)} \pm 0.10\text{(syst)}$, which is compatible with a $p$-value of 4.6% with the standard model prediction of 0.44.

1 Introduction

The top quark is the heaviest elementary particle discovered so far. Its lifetime ($\sim 4 \times 10^{-25} \text{s}$) is much shorter than the typical timescales of quantum chromodynamics (QCD). It is therefore the only quark that decays through electroweak interactions before hadronising. Furthermore, the parity-violating nature of the V-A electroweak interaction at the $Wtb$ vertex means that only left-handed quarks are expected at this vertex. Thus, top quark decay products retain memory of the top quark spin orientation in their angular distributions. This fact turns the top quark into a powerful probe of the structure of the electroweak $Wtb$ vertex.

In electroweak $t$-channel single top quark production, shown in figure 1, the standard model (SM) predicts that produced top quarks are highly polarised, as a consequence of the V-A coupling structure, along the direction of the momentum of the spectator quark.
(q'), which recoils against the top quark [1, 2]. However, new physics models could also lead to a depolarisation in production by altering the coupling structure [3–6].

In this analysis, the top quark spin asymmetry

\[ A_X = \frac{1}{2} P_t \alpha_X = \frac{N(\uparrow) - N(\downarrow)}{N(\uparrow) + N(\downarrow)} \]

is used to probe the coupling structure, where \( P_t \) represents the top quark polarisation in production and \( \alpha_X \) denotes the degree of the angular correlations of one of its decay products, denoted \( X \) (where for this analysis \( X = \mu \)), with respect to the spin of the top quark, the so-called spin-analysing power. The variables \( N(\uparrow) \) and \( N(\downarrow) \) are defined, for each top quark decay product from the decay chain \( t \rightarrow bW \rightarrow b\mu\nu \), as the number of instances in which that decay product is aligned or antialigned, respectively, relative to the direction of the recoiling spectator quark momentum.

In this analysis, the muon is chosen as the top quark spin analyser because leptons have the highest spin-analysing power and since the muon identification efficiency is very high in the CMS detector. The spin-analysing power is exactly 1 at leading order (LO) in the SM. Its value can be modified by new physics that may be characterised by anomalous top quark coupling models arising from an effective extension of the coupling structure of the Wtb vertex [5].

The measurement of the top quark spin asymmetry, measured in \( t \)-channel single top quark events with one isolated muon in the final state, is the subject of this paper. The asymmetry is measured for top quark and antiquark events separately to be sensitive to potential CP-violation, which is predicted in some new physics models.

The analysis strategy is as follows: after applying an event selection designed to obtain a set of relatively high purity \( t \)-channel single top quark events, the signal and background composition of data is estimated using a binned likelihood fit. A top quark candidate is then reconstructed and the angle between the muon and the recoiling jet calculated in the top quark rest frame.

An unfolding technique is applied to obtain a differential cross section measurement of this angular distribution at parton level. From the unfolded distribution, the top quark spin asymmetry, which is directly related to the polarisation through eq. (1.1), is calculated for top quark and antiquark events, and their combination.
2 The CMS detector and event reconstruction

The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the solenoid volume are a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter (ECAL), and a brass and scintillator hadron calorimeter (HCAL), each composed of a barrel and two endcap sections. Muons are measured in gas-ionisation detectors embedded in the steel flux-return yoke outside the solenoid. Extensive forward calorimetry complements the coverage provided by the barrel and endcap detectors. A more detailed description of the CMS detector, together with a definition of the coordinate system used and the relevant kinematic variables, can be found in ref. [7].

The particle flow algorithm [8, 9] reconstructs and identifies each individual particle in an event with an optimised combination of information from the various elements of the CMS detector. The energy of photons is directly obtained from the ECAL measurement. The energy of electrons is determined from a combination of the electron momentum at the primary interaction vertex, as determined by the tracker, the energy of the corresponding ECAL cluster, and the energy sum of all bremsstrahlung photons spatially compatible with originating from the electron track. The energy of muons is obtained from the curvature of the corresponding track. The energy of charged hadrons is determined from a combination of their momentum measured in the tracker and the matching ECAL and HCAL energy deposits, corrected for the response function of the calorimeters to hadronic showers. Finally, the energy of neutral hadrons is obtained from the corresponding corrected ECAL and HCAL energy. To mitigate the effect of pileup, i.e. additional proton-proton collisions whose signals in the detector sum to the products of the primary interaction that triggered the event, charged particles associated to non-leading primary vertices are vetoed.

The missing transverse momentum vector, \( \vec{p}_T \), is defined as the projection onto the plane perpendicular to the beams of the negative vector sum of the momenta of all reconstructed particles in an event. Its magnitude is referred to as missing transverse energy (\( E_T \)).

3 Data and simulated samples

This study is based on the proton-proton collision data set recorded by the CMS detector at the CERN LHC in 2012 at a centre-of-mass energy 8 TeV, corresponding to an integrated luminosity of \( 19.7 \pm 0.5 \text{ fb}^{-1} \) [10].

Single top quark \( t \)-channel events from Monte Carlo (MC) simulation are generated with the next-to-leading-order (NLO) MC generator POWHEG 1.0 [11–13], interfaced with PYTHIA 6.4 [14] for the parton showering, in which \( \tau \) lepton decays are modelled with TAUOLA [15]. The 5-flavour scheme (5FS) is used in the generation, i.e. inherent \( b \) quarks are considered among the incoming particles as in figure 1 (left). As an alternative NLO generator, used to assess the dependence of the analysis on the modelling of signal, we use amC@NLO 2.1.2 [16] interfaced with PYTHIA 8.180 [17], with the 4-flavour scheme (4FS), i.e. \( b \) quarks in the initial state are only produced via gluon splitting as in figure 1 (right). The measured results are compared with predictions from the aforementioned NLO generators.
and the LO generator CompHEP 4.5 [18], interfaced with Pythia 6, with a matching procedure between LO 5FS and 4FS diagrams based on the transverse momentum $p_T$ of the associated b quark [19]. Special samples are generated using CompHEP 4.5 including a Wtb coupling with anomalous structure.

Several SM processes are taken into account as backgrounds in the analysis. The POWHEG 1.0 generator interfaced with Pythia 6 is also used to model the W-associated (tW) and s-channel single top quark background events. The t\overline{t}, W boson in association with jets (W+jets), and Drell-Yan in association with jets (Z/\gamma^{*}+jets) processes are generated with MadGraph 5.1 [20] interfaced with Pythia 6. Tauola is used to simulate $\tau$ lepton decays. Up to three (four) additional partons are generated at matrix-element (ME) level in $t\overline{t}$ (W+jets and Z/\gamma^{*}+jets) events. A procedure, implemented during event generation, based on the so-called “MLM prescription” [21, 22], avoids double counting jets generated simultaneously by the ME and by the parton shower (PS) simulations. An alternative sample of W+jets generated with Sherpa 1.4.0 at NLO [23, 24] is used to compare the modelling of this background. Diboson production (WW, WZ, ZZ) is simulated using Pythia 6. Multijet events (i.e. events with the muon not originating from a leptonically decaying W or Z boson) are modelled using statistically independent samples in data, as detailed in section 6.1. Other special samples of signal and background are generated with different values for generator parameters (e.g. top quark mass, renormalisation and factorisation scales, etc.), and used to estimate the corresponding systematic uncertainties.

All single top quark processes are normalised to approximate next-to-next-to-leading-order (NNLO) predictions [25] ($\sigma_{t\text{-channel}} = 87.1$ pb, $\sigma_{s\text{-channel}} = 5.55$ pb, $\sigma_{tW} = 22.2$ pb). Top quark pair production is normalised to a complete NNLO prediction in QCD that includes soft gluon resummation to next-to-next-to-leading-log order, as calculated with the TOP++2.0 program [26] ($\sigma_{tt} = 252.9$ pb). The W+jets and Z/\gamma^{*}+jets production cross sections times branching fraction are calculated at NNLO with Fewz [27], $B(W \rightarrow \ell$+$\nu) = 37.509$ pb, and $B(Z/\gamma^{*} \rightarrow \ell^{+}\ell^{-}) = 3504$ pb at a generator-level threshold of $m_{\ell^{+}\ell^{-}} > 50$ GeV, where $\ell = e, \mu, \text{or} \tau$. The diboson cross sections are calculated at NLO with MCFM 5.8 [28] ($\sigma_{WW} = 54.8$ pb, $\sigma_{WZ} = 33.2$ pb, and $\sigma_{ZZ} = 8.1$ pb).

The effect of pileup is evaluated using a simulated sample of minimum-bias events produced using Pythia 6, superimposed onto the events in the simulated samples described above, taking into account in-time and out-of-time pileup contributions. The events are then reweighted to reproduce the true pileup distribution inferred from the data. The procedure is validated by comparing the number of observed primary vertices between data and simulation.

All generated events undergo a full Geant4 [29] simulation of the detector response.

4 Event selection

The study presented here focuses on the $t \rightarrow bW \rightarrow b\ell \nu$ decay channel. Signal events are characterised by exactly one isolated muon, large $E_T$ (originating from the neutrino in the leptonic decay of the W boson), one central b jet from the top quark decay, and an additional untagged jet ($j'$) from the spectator quark ($q'$) from the hard-scattering
process, which is preferentially produced in the forward region of the detector. A second b jet produced in association with the top quark can also be present in the detector, although it yields a softer $p_T$ spectrum relative to the b jet from the top quark decay. The event selection applied in the measurement of the production cross section in the same channel [30] is closely followed.

Trigger selection is based on the presence of at least one isolated muon with $p_T > 24$ GeV and $|\eta| < 2.1$.

One isolated muon candidate is required to originate from the leading primary vertex, which is defined as the vertex with the largest value of the summed $p_T^2$ of its associated charged tracks. Muon candidates are accepted if they pass the following requirements: $p_T$ of at least 26 GeV, $|\eta| < 2.1$, quality and identification criteria optimised for the selection of prompt muons, and a relative isolation requirement of $I_{rel} < 0.12$. The relative isolation, $I_{rel}$, is defined by the scalar sum, divided by the $p_T$ of the muon, of the transverse energies deposited by stable charged hadrons, photons, and neutral hadrons where deposits linked to pileup are subtracted within a cone of radius $\Delta R = \sqrt{\Delta \eta^2 + \Delta \phi^2} = 0.4$ (where $\phi$ is the azimuthal angle in radians) around the muon direction. Events are rejected if an additional muon or electron candidate is present. The selection requirements for these additional electrons/muons are as follows: looser identification and isolation criteria, $p_T > 10$ (20) GeV for muons (electrons), and $|\eta| < 2.5$.

Jets are reconstructed from the particle-flow candidates and clustered with the anti-$k_T$ algorithm [31, 32] with a distance parameter of 0.5. The influence of pileup is mitigated using the charged hadron subtraction technique [33]. The jet momentum is determined as the vectorial sum of all particle momenta in the jet. An offset correction is applied to the transverse jet momenta to account for contributions from pileup. Further corrections are applied to account for the non-flat detector response in $\eta$ and $p_T$ of the jets. The corrected jet momentum is found from simulation to be within 5% to 10% of the true momentum over the whole $p_T$ spectrum and detector acceptance. The corrections are propagated to the measured $\vec{p}_T$ as it depends on the corrected jets through the clustered tracks. Additional selection criteria are applied to each event to remove spurious jet-like features originating from isolated noise patterns in certain HCAL regions. The analysis considers jets within $|\eta| < 4.5$ whose calibrated transverse energy is greater than 40 GeV. The event is accepted for further analysis only if at least two such jets are present.

To reduce the large background from W+jets events, a b tagging algorithm based on combined information from secondary vertices and track-based lifetimes [34, 35] is used. A tight selection is applied on the b tagging discriminant, which corresponds to an efficiency of $\approx 50\%$ for jets originating from true b quarks and a mistagging rate of $\approx 0.1\%$ for other jets in the signal simulation. The b tagging performance in simulation is corrected to better match the performance observed in data [35], using scale factors that depend on the $p_T$ and $\eta$ of the selected jets.

Corrections are applied to the simulation, where necessary, to account for known differences relative to data. Single-muon trigger efficiencies and lepton reconstruction and identification efficiencies are estimated with a “tag-and-probe” method [36, 37] from Z/$\gamma^*$+jets data. B tagging and misidentification efficiencies are estimated by dedicated analyses per-
formed with statistically independent selections [35]. A smearing of the jet momenta is applied to account for the known difference in jet energy resolution (JER) in simulation compared to data [38]. The effects of all these corrections are found to be small.

To classify signal and control regions, different event categories, denoted “N jets M tag(s)” are defined, where N is the total number of selected jets (2 or 3) and M is the number of those jets passing additionally the b tagging requirements (0, 1, or 2). The “2 jets 1 tag” category defines the region used for signal extraction, whereas the other categories, enriched in background processes with different compositions, are used for the control samples discussed in section 6. The “2 jets 1 tag” category is separated into a control region and a signal region, depending on the value of a multivariate discriminant, described below.

In the “2 jets 1 tag” category, a top quark candidate is reconstructed from the b jet, the muon, and a neutrino candidate. A neutrino candidate is constructed as described in ref. [39]. The neutrino $p_T^{\nu}$ momentum is found by requiring a W boson mass constraint from momentum conservation using the muon and missing transverse momenta. In the other categories, the jet with the highest value of the b tagging discriminant is used for top quark reconstruction.

Multijet events are suppressed by setting a threshold on the output of a dedicated boosted decision tree (BDT$_{\text{multijet}}$), trained using the following input variables:

- the missing transverse energy, $E_T^{miss}$;
- the invariant mass of the top quark candidate, $m_{biv}$;
- the transverse mass of the W boson candidate, $m_T(W) = \sqrt{(p_T^{\mu} + E_T^{miss})^2 - (p_T^{\nu} + p_T^{T,y})^2}$;
- the transverse momentum of the untagged jet, $p_T^{j_0}$;
- the event isotropy, defined as $(S_{\text{max}} - S_{\text{min}})/S_{\text{max}}$ with $S = \sum_{i=1}^{\mu,\text{jets}} |\vec{n} \cdot \vec{p}_i|$, where the unit vector in the transverse $r-\phi$ plane, $\vec{n} = (\cos \phi, \sin \phi)$, can be chosen to either maximise or minimise $S$.

To reject background events, a second boosted decision tree, BDT$_{W/t\bar{t}}$, is used to separate signal from $t\bar{t}$ and W+jets events. Training is performed with the following input observables:

- the invariant mass of the top quark candidate, $m_{biv}$;
- the absolute pseudorapidity of the untagged jet, $|\eta_j|$;
- the absolute pseudorapidity of the b-tagged jet, $|\eta_b|$;
- the invariant mass of the b-tagged jet from the summed momenta of the clustered tracks, $m_h$;
Figure 2. Distributions of the BDT\textsubscript{multijet} discriminant in the (left) “2jets 1tag” and (right) “3jets 2tags” categories. The predictions are normalised to the results of the fit described in section 7. The bottom panels in both plots show the ratio between observed and predicted event counts, with a shaded area to indicate the systematic uncertainties affecting the background prediction and vertical bars indicating statistical uncertainties.

- the transverse momentum of the muon, $p_T^\mu$;
- the transverse momentum of the b-tagged jet, $p_T^b$;
- the transverse mass of the W boson candidate;
- the missing transverse energy, $E_T$;
- the total invariant mass of the top quark candidate and the untagged jet system, $s$;
- the transverse momentum of the hadronic final-state system, $H_T = (\vec{p}_b + \vec{p}_j)_{\perp}$.

By construction, the BDT discriminant ranges between +1 and −1, with the algorithm trained such that the resulting distribution peaks at a high BDT discriminant value for signal-like events and at a low value for background-like events. The distribution of the BDT\textsubscript{multijet} discriminant is shown in figure 2 in two categories, with the multijet events shape and normalisation extracted as described in section 6.1. To reject multijet events, we only use events that pass the threshold BDT\textsubscript{multijet} discriminant > 0.15 in the analysis. Figure 3 shows the distribution of the BDT\textsubscript{W/tt} discriminant in the “2jets 1tag” and “3jets 2tags” categories after applying the selection requirement on the BDT\textsubscript{multijet} discriminant.

Figure 4 shows the distributions of the $|\eta|^2$ and $m_{\tilde{b}\tilde{H}}$ variables in the “2jets 1tag” category. These variables have the highest ranking in the decision of the BDT\textsubscript{W/tt}.

To select a signal-enhanced phase space, an additional selection is imposed on the BDT\textsubscript{W/tt} discriminant. The optimal working point is found to be BDT\textsubscript{W/tt} discriminant > 0.45 by studying the analysis sensitivity with pseudo-data from simulated events.

All BDT input variables are found to be well modelled by the MC simulation. The BDTs are trained and tested on statistically independent samples, with no overtraining observed.
5 The \( \cos \theta^* \) distribution of top quark decay products

The angle between a top quark decay product \( X \) (W, \( \ell \), v, or b) and an arbitrary polarisation axis \( \vec{s} \) in the top quark rest frame, \( \theta^*_X \), is distributed according to the following differential cross section:

\[
\frac{1}{\sigma} \frac{d\sigma}{d \cos \theta^*_X} = \frac{1}{2} (1 + P^{(s)}_1 \alpha_X \cos \theta^*_X) = \left( \frac{1}{2} + A_X \cos \theta^*_X \right).
\]  

The variable \( P^{(s)}_1 \) denotes the single top quark polarisation along the chosen axis, and \( \alpha_X \) the spin-analysing power as defined in section 1. In the SM, the top quark spin tends to be aligned with the direction of the spectator quark momentum, resulting in a high degree of polarisation. Hence, an excess of events where the spectator quark momentum is antialigned with the top quark spin would clearly indicate an anomalous coupling structure.
Single top quark polarisation is studied in the $t$-channel process through the angular asymmetry $A_\mu$ of the muon, with the polarisation axis defined as pointing along the untagged jet ($j'$) direction in the top quark rest frame.

Figure 5 shows the reconstructed distribution of $\cos \theta_\mu^*$ in the “2jets 1tag” (for $\text{BDT}_{W/\tau} > 0.45$) and “3jets 2tags” categories. The observed distribution is expected to differ from the parton-level prediction because of detector effects and the kinematic selection applied, with the most significant effect being the relatively small number of selected events close to $\cos \theta_\mu^* = 1$. An overall trend in the ratio between data and simulation is observed that suggests a slightly less asymmetric shape than predicted by the SM.

In this analysis, a $\chi^2$-fit is performed of the unfolded $\cos \theta_\mu^*$ differential cross section to estimate $A_\mu$ based on eq. (5.1).

6 Studies of background modeling

Statistically independent control samples are used for several purposes in this analysis. Samples in which the isolation requirement on the muon is inverted are used to extract templates for estimating the contamination by multijet events, while samples with different jet and b-tagged jet multiplicities are used to validate the simulation of W+jets and $t\bar{t}$ events, or to provide additional constraints on the in situ determination of background and signal strengths relative to the SM.

6.1 Estimation of multijet events background

The yield of the multijet events background in the different categories is measured by performing fits to the BDT$_{\text{multijet}}$ discriminant distributions for each “$N\text{jet }M\text{tag}$” category where a significant contamination from this process is expected. A binned maximum-likelihood (ML) fit to the data is performed using two components: multijet events (unconstrained) and the sum of all other processes (constrained to be within ±20% of the
expected yield using a log-normal prior that the fit constrains further). The latter category includes the signal. A normalised distribution (template) for the sum of other processes is taken from simulation. The multijet events template is obtained from a statistically independent multijet-enriched data sample with an inverted isolation requirement, as defined above. It is verified that the BDT_{multijet} discriminant distributions for multijet events are not significantly affected by this altered event selection.

Uncertainties on the multijet events yields are estimated conservatively to be ±50%. In addition, an uncertainty on the shape is taken into account by using a modified inverted isolation requirement. Together, these are used to estimate the systematic uncertainty associated with this procedure, as discussed in section 9.

6.2 W+jets model validation and correction

After estimating the multijet events contribution to the signal region, the agreement between the expectations and the data is verified in several control regions for all the BDT_{W/\tau} inputs, for the BDT_{W/\tau} response, for cos(\theta_\mu^*) and for a number of additional variables. Among all the control regions considered, cos(\theta_\mu^*) and \pT of the reconstructed W boson are observed to be mismodeled in the “2jets 0tags” control region; this region is expected to be enriched in W+jets events.

A similar disagreement between data and the MadGraph prediction in the cos(\theta_\mu^*) distribution is observed in data collected at \sqrt{s} = 7 TeV in the context of a different analysis [30]. Investigations using different MC generators and their associated settings show that Sherpa [40] provides a better description of cos(\theta_\mu^*) in this control region at both centre-of-mass energies.

Although this control region is not used in the fit, additional investigations have been performed to check whether this mismodeling can potentially affect the signal region. The MadGraph and Sherpa samples are found to differ mostly in the cos(\theta_\mu^*) distribution for events with a W boson produced in association with jets from gluon fragmentation, which constitutes a major component of the “2jets 0tags” region, but is a very small fraction of the “2jets 1tag” signal region.

In the kinematic region studied by this analysis, MadGraph reproduces the W+jets kinematic distributions better than Sherpa. Moreover, for computational reasons, the approximation of using b and c quarks as massless in the generation of the Sherpa samples causes the relative fraction of heavy quarks to be unrealistically large. For these reasons, MadGraph is chosen as the default generator in this analysis, and a reweighting of the W+jets events simulated with MadGraph is performed in all signal and control regions using the event ratio between the two generators as a function of cos(\theta_\mu^*), separately for each flavour component, in the “2jets 0tags” control region.

6.3 t\bar{t} model validation

To validate the modelling of t\bar{t} events, we compare simulated events to data in the “3jets 2tags” control region for the most relevant observables. In particular, figures 2 (right), 3 (right), and 5 (right) show the BDT_{multijet} and BDT_{W/\tau} discriminants,
and the $\cos\theta_\mu^*$ distribution, respectively. This control region is also used in the fit described in section 7.

The MadGraph model of $t\bar{t}$ production is known to predict a harder top quark $p_T$ ($p_T^t$) spectrum than observed in data [41, 42]. The spectrum of generator-level top quarks in $t\bar{t}$ events is therefore reweighted so that it reproduces the measured differential cross section as a function of $p_T^t$.

In conclusion, the $t\bar{t}$ modelling provided by MadGraph after applying the $p_T^t$ reweighting is found to be in reasonable agreement with data.

7 Extraction of signal and background yields

The signal and background components are estimated by means of a simultaneous ML fit to the distribution of the BDT$_{W/t\bar{t}}$ discriminant in the “2jets 1tag” and “3jets 2tags” regions. The inclusion of the $t\bar{t}$-dominated “3jets 2tags” region in the fit provides an additional constraint on the $t\bar{t}$ background. This also reduces correlations of the estimated $t\bar{t}$ yield with other contributions.

For all background processes, except the multijet events background, templates from the MC samples are used. The multijet events template is obtained from data by inverting the isolation selection, as discussed previously, and its normalisation is kept fixed to the estimated yield described in section 6.1. To reduce the number of free parameters, several processes that have a similar distribution in both $\cos\theta_\mu^*$ and the BDT$_{W/t\bar{t}}$ discriminant are merged into a single contribution:

- Signal: $t$-channel single top quark production, treated as unconstrained.
- Top quark background: $t\bar{t}$, $s$-channel and $tW$ single top quark production, with their relative fractions taken from simulation; a constraint of $\pm20\%$ using a log-normal prior is applied.
- $W/Z$/diboson: $W$+jets, $Z/\gamma^{*}$+jets, and diboson production, with their relative fractions taken from simulation, have a constraint of $\pm50\%$ using a log-normal prior.

The results of the three fits, and the post-fit uncertainties for top quark events, top antiquark events, and their combination, are presented in table 1 as scale factors to be applied to simulation yields, while table 2 shows the number of events exceeding the threshold on the BDT$_{W/t\bar{t}}$ discriminant >0.45. The number of top quark events is greater than the number of top antiquark events due to the up-quark density being larger than either the down-quark or up-antiquark densities at large values of Bjorken $x$ in the incoming protons.

8 Unfolding

An unfolding procedure is used to determine the differential cross section as a function of $\cos\theta_\mu^*$ at the parton level. It accounts for distortions from detector acceptance, selection efficiencies, imperfect reconstruction of the top quark candidate, and the approximation made in treating the direction of the untagged jet as the spectator quark direction.
Table 1. Estimated scale factors and uncertainties from the simultaneous maximum-likelihood fit to the distribution of the $\text{BDT}_{W/t\bar{t}}$ discriminant in the “2jets 1tag” and “3jets 2tags” categories.

In simulation, the parton-level definition of $\cos \theta^{*}_\mu$ is defined based on the generated muon from the decay chain of a top quark or antiquark and the spectator quark scattering off the top quark or antiquark via virtual W boson exchange, with all momenta boosted into the rest frame of the generated top quark or antiquark. To preserve the spin information from the W decay, the response matrix takes into account the case in which the muon is from $W \rightarrow \tau \nu \rightarrow \mu \nu \nu$ decay by unfolding the angular distribution to the $\tau$ lepton. Prior to unfolding, remaining background contributions are subtracted from the reconstructed data, using the fitted number of events and their uncertainties, estimated in section 7.

After the background subtraction, an unfolding procedure [43] is applied. At its core is the application of a matrix inversion using second derivatives for regularisation. A detailed description of the procedure can be found in the $t\bar{t}$ charge asymmetry analysis [44], performed previously by CMS, which utilises the same method.

The performance of the unfolding algorithm is checked using sets of pseudo-experiments. Pull distributions show no sign that the uncertainties are treated incorrectly.
A bias test is performed by injecting anomalous Wtb-vertex coupling events as pseudo-data, generated with CompHEP \cite{18,19}. This test verifies that, with the analysis strategy described here, it is possible to measure different asymmetries correctly, and with only a small bias that will be accounted for as a systematic uncertainty.

The value of $A_\mu$ is extracted using a $\chi^2$-fit of the unfolded $\cos \theta^*_W$ distribution, under the assumption that eq. (5.1) is valid. The fit takes into account the bin-by-bin correlations that are induced in the unfolding procedure.

An alternative procedure, based on analytic matrix inversion with only two bins in the $\cos \theta^*_W$ distribution (corresponding to forward- and backward-going muons), is used as a crosscheck. Although the results of the two methods are in agreement, the expected precision of the analytic matrix inversion is slightly worse when tested using pseudo-data.

9 Systematic uncertainties

The differential cross section and asymmetry measurement presented in this paper can be affected by several sources of systematic uncertainty. To evaluate the impact of each source, we perform a new background estimation and repeat the measurement with systematically shifted simulated templates and response matrices. The expected systematic uncertainty for each source is taken to be the maximal shift in the values of the asymmetry between the nominal asymmetry and the one measured using the shifted templates.

ML fit uncertainty: this uncertainty is determined by propagating the uncertainty associated with the background normalisation from the maximum-likelihood fit through the unfolding procedure.

Other background fractions: a specific uncertainty is assigned to the fraction of each minor process that is combined with similar and larger processes in the fit. These are dibosons and $Z/\gamma^*+\text{jets}$ production for the $W/Z$/diboson component, and the $tW$ and $s$-channel production for the top quark component. A yield uncertainty of 50\% is used for each of the templates.

Multijet events background shape: a shape uncertainty is taken into account by varying the range of inverted isolation requirement used to extract the templates for estimating this background contribution.

Multijet events background yield: a 50\% uncertainty is assigned to the yield obtained from the multijet events fit.

b tagging: the uncertainties in the b tagging and mistagging efficiencies for individual jets as measured in data \cite{35} are propagated to the simulation event weights.

Detector-related jet and $E_T$ effects: all reconstructed jet four-momenta in simulated events are changed simultaneously according to the $\eta$- and $p_T$-dependent uncertainties in the jet energy scale \cite{38}. The changes in jet four-momenta are also propagated to $E_T$. In addition, the effect on the measurement of $E_T$ arising from the 10\% uncertainty associated with unclustered energy deposits in the calorimeters is estimated after subtracting from
\( \slashed{E}_T \) all jets and leptons. An extra uncertainty accounts for the known difference in JER relative to data [38].

**Pileup:** a 5\% uncertainty is applied to the average expected number of pileup interactions in order to estimate the uncertainty arising from the modelling of pileup.

**Muon trigger, identification, and isolation efficiencies:** a systematic uncertainty of 1\% is applied independently to the muon trigger, identification, and isolation efficiencies. These uncertainties cover the efficiency differences between the phase space regions sampled by the present selection and by the selection of \( Z/\gamma^* + \text{jets} \) events for the tag-and-probe procedure.

**\( \bar{t}t \) top quark \( p_T \) reweighting:** the MadGraph model for \( \bar{t}t \) production is known to predict a harder \( p_T \) spectrum compared to that observed in data [41, 42]. Although the correlation with other uncertainty sources is not clear, the spectrum of generator-level top quarks in \( \bar{t}t \) events is reweighted to the measured differential cross section and an additional systematic uncertainty from this reweighting by either doubling or not using any reweighting is applied.

**W boson \( p_T \) reweighting in W+jets:** the MadGraph model for W+jets events predicts a \( p_T \) spectrum of the reconstructed W boson candidate that does not agree with data in the “2 jets 0 tags” control region. The distribution is reweighted to data (after subtraction of other processes) and the difference is taken as a systematic uncertainty.

**cos \( \theta^*_\mu \) reweighting in W+jets:** the uncertainty associated with the reweighting procedure presented in section 6.2 is estimated conservatively by comparing the result after \( \cos \theta^*_\mu \) shape reweighting with that determined with no weighting applied. The difference between the two is then symmetrised and taken as the uncertainty. An additional uncertainty is assigned to the fraction of W+jets events in which jets arise from heavy flavours. This uncertainty is taken into account by scaling its contribution by \( \pm50\% \) relative to the prediction by MadGraph.

**Unfolding bias:** a test of the analysis shows a small bias when injecting events with anomalous couplings as pseudo-data. This is treated as an additional systematic uncertainty in the asymmetry measurement.

**Generator model:** the nominal result is compared with the one obtained using an unfolding matrix from a signal sample generated with aMC@NLO, interfaced with Pythia 8 for parton showering.

**Top quark mass:** additional samples of \( \bar{t}t \) and signal events are generated with the top quark mass changed by \( \pm3 \) GeV. These are used to determine the uncertainty arising from our knowledge of the top quark mass. This is a conservative estimate as the current world average is \( 173.3 \pm 0.8 \) GeV [45].
Parton distribution functions: the uncertainty due to the choice of the set of parton distribution functions (PDF) is estimated by reweighting the simulated events with each of the 52 eigenvectors of the CT10 collection [46], and additional eigenvectors corresponding to variation of the strong coupling, as well as using the central sets from the MSTW2008CPdeut [47] and NNPDF23 [48] collections. The LHAPDF [49] package is used for the reweighting.

Renormalisation and factorisation scales: the uncertainties in the renormalisation and factorisation scales (set to a common scale equal to the momentum transfer $Q$ in the event) are evaluated for signal, $t\bar{t}$ and W+jets independently, by doubling or halving the value of the scale. For the signal, a reweighting procedure is applied to simulated events, using the simplification of neglecting the scale dependence of the parton shower (PS). Since the signal process does not contain a QCD vertex at LO in the 5FS, the dependence of its cross section with scale $Q$ can be written as

$$\sigma^{LO}_{\text{tech.}}(Q) = \int_0^1 dx_1 f_{PDF}(x_1; Q^2) \int_0^1 dx_2 f_{PDF}(x_2; Q^2) \hat{\sigma}(x_1, x_2),$$

where $x_i$ are the momentum fractions of the two partons in the colliding protons, $f_{PDF}(x_i; Q^2)$ is the PDF, and $\hat{\sigma}(x_1, x_2)$ denotes the partonic cross section. The event reweighting to a different scale $Q'$ is then defined using a factor

$$w_{Q\rightarrow Q'}(x_1, x_2) = \frac{f_{PDF}(x_1, Q'^2)}{f_{PDF}(x_1, Q^2)} \frac{f_{PDF}(x_2, Q'^2)}{f_{PDF}(x_2, Q^2)}.$$  

Dedicated simulated samples with doubled and halved scales are used to verify the validity of the approximation of ignoring the effect of scale in PS simulation for the signal process. The reweighting is preferred over use of these dedicated samples because of their limited number of events.

For the $t\bar{t}$ and W+jets backgrounds, a lower threshold is applied to the BDT $W=tt$ discriminant in simulated samples that have a changed $Q$ scale to increase the number of selected events. This provides a $\cos\theta_W$ distribution that agrees, within the limited statistical uncertainty of the simulation, with the shape obtained by applying the nominal BDT $W=tt$ discriminant threshold.

Matrix element/parton shower matching threshold: the impact of the choice of ME/PS matching threshold in the MLM procedure is evaluated independently for $t\bar{t}$ and W+jets processes, using dedicated samples in which the threshold is either doubled or halved.

Limited number of simulated events: the uncertainty associated with the limited amount of simulated events used in forming the templates is taken into account at all stages of the analysis, i.e. both in terms of fluctuations in the background and in determining the elements of the migration matrix. The limited number of simulated events can also influence the estimation of other systematic uncertainties, potentially leading to an overestimation of the associated uncertainties.

Table 3 shows the impact of the different sources of systematic uncertainties on the asymmetry measurements.

**Table 3.** List of systematic uncertainties and their induced shifts from the nominal measured asymmetry for the top quark ($\delta A_m(t)$), antiquark ($\delta A_m(\bar{t})$), and their combination ($\delta A_m(t + \bar{t})$).
Figure 6. The normalised differential cross sections as a function of unfolded $\cos \theta^*_t$ for (left) top quark and (right) antiquark compared to the predictions from POWHEG, aMC@NLO, and CompHEP. The inner (outer) bars represent the statistical (total) uncertainties.

10 Results

Figures 6 and 7, respectively, show the differential cross sections obtained from the unfolding procedure for single top quark and antiquark production, and for their combination, with a comparison to the SM expectations from POWHEG, aMC@NLO, and CompHEP. These generators agree well in their predictions of $A_\mu$. Uncertainties arising from the renormalisation and factorisation scale and PDF variations have been found to be negligible for the predicted differential distributions and are therefore not shown.

The asymmetry $A_\mu$ is extracted from the differential cross section according to eq. (5.1), taking into account correlations. Using this procedure, we obtain:

$$A_\mu(t) = 0.29 \pm 0.03 \text{ (stat)} \pm 0.10 \text{ (syst)} = 0.29 \pm 0.11,$$

$$A_\mu(\bar{t}) = 0.21 \pm 0.05 \text{ (stat)} \pm 0.13 \text{ (syst)} = 0.21 \pm 0.14,$$

$$A_\mu(t + \bar{t}) = 0.26 \pm 0.03 \text{ (stat)} \pm 0.10 \text{ (syst)} = 0.26 \pm 0.11,$$

where the combined result is compatible with a $p$-value of $p(\text{data}\mid\text{SM}) = 4.6\%$, which corresponds to 2.0 standard deviations compared to the expected SM asymmetry of 0.44 as predicted by POWHEG (NLO). Alternatively, the compatibility of the combined result with the hypothetical case of $A_\mu = 0$ is smaller, yielding a $p$-value of $p(\text{data}\mid A_\mu = 0) = 0.7\%$, and corresponding to 2.7 standard deviations. The SM asymmetry predictions for simulated top quark and antiquark events are equal, while [1] predicts an $\mathcal{O}(1\%)$ difference, which is small compared to the precision of the current measurement.

As a crosscheck, an analytic 2-bin unfolding is also performed, which yields the numbers $N(\uparrow)$ and $N(\downarrow)$ defined in eq. (1.1). This gives a compatible but slightly less precise value for $A_\mu$ of:

$$A_\mu(t + \bar{t}) = 0.28 \pm 0.03 \text{ (stat)} \pm 0.1 \text{ (syst)} = 0.28 \pm 0.12.$$
The first measurement of the top quark spin asymmetry, sensitive to the top quark polarisation, in $t$-channel single top quark production has been presented. This measurement is based on a sample of pp collisions at a centre-of-mass energy of 8 TeV, corresponding to an integrated luminosity of 19.7 $fb^{-1}$.

The asymmetry, $A_\mu$, is obtained by performing a differential cross section measurement of $\cos \theta_\mu$, between forward- and backward-going muons with respect to the direction of the spectator quark in the top quark rest frame. The measurement yields $A_\mu = 0.26 \pm 0.03 \text{(stat)} \pm 0.10 \text{(syst)} = 0.26 \pm 0.11$, which is compatible with a $p$-value of 4.6%, equivalent to 2.0 standard deviations, with the standard model expectation.

The asymmetry observed in data is smaller than the prediction. Separate results from exclusive top quark or antiquark events are compatible within the uncertainties. This difference cannot be explained by any single source of systematic uncertainty considered in this analysis.

Acknowledgments

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centres and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction
operation of the LHC and the CMS detector provided by the following funding agencies: the Austrian Federal Ministry of Science, Research and Economy and the Austrian Science Fund; the Belgian Fonds de la Recherche Scientifique, and Fonds voor Wetenschappelijk Onderzoek; the Brazilian Funding Agencies (CNPq, CAPES, FAPERJ, and FAPESP); the Bulgarian Ministry of Education and Science; CERN; the Chinese Academy of Sciences, Ministry of Science and Technology, and National Natural Science Foundation of China; the Colombian Funding Agency (COLCIENCIAS); the Croatian Ministry of Science, Education and Sport, and the Croatian Science Foundation; the Research Promotion Foundation, Cyprus; the Ministry of Education and Research, Estonian Research Council via IUT23-4 and IUT23-6 and European Regional Development Fund, Estonia; the Academy of Finland, Finnish Ministry of Education and Culture, and Helsinki Institute of Physics; the Institut National de Physique Nucléaire et de Physique des Particules / CNRS, and Commissariat à l’Énergie Atomique et aux Énergies Alternatives / CEA, France; the Bundesministerium für Bildung und Forschung, Deutsche Forschungsgemeinschaft, and Helmholtz-Gemeinschaft Deutscher Forschungszentren, Germany; the General Secretariat for Research and Technology, Greece; the National Scientific Research Foundation, and National Innovation Office, Hungary; the Department of Atomic Energy and the Department of Science and Technology, India; the Institute for Studies in Theoretical Physics and Mathematics, Iran; the Science Foundation, Ireland; the Istituto Nazionale di Fisica Nucleare, Italy; the Ministry of Science, ICT and Future Planning, and National Research Foundation (NRF), Republic of Korea; the Lithuanian Academy of Sciences; the Ministry of Education, and University of Malaya (Malaysia); the Mexican Funding Agencies (CINVESTAV, CONACYT, SEP, and UASLP-FAI); the Ministry of Business, Innovation and Employment, New Zealand; the Pakistan Atomic Energy Commission; the Ministry of Science and Higher Education and the National Science Centre, Poland; the Fundação para a Ciência e a Tecnologia, Portugal; JINR, Dubna; the Ministry of Education and Science of the Russian Federation, the Federal Agency of Atomic Energy of the Russian Federation, Russian Academy of Sciences, and the Russian Foundation for Basic Research; the Ministry of Education, Science and Technological Development of Serbia; the Secretaría de Estado de Investigación, Desarrollo e Innovación and Programa Consolider-Ingenio 2010, Spain; the Swiss Funding Agencies (ETH Board, ETH Zurich, PSI, SNF, UniZH, Canton Zurich, and SER); the Ministry of Science and Technology, Taipei; the Thailand Center of Excellence in Physics, the Institute for the Promotion of Teaching Science and Technology of Thailand, Special Task Force for Activating Research and the National Science and Technology Development Agency of Thailand; the Scientific and Technical Research Council of Turkey, and Turkish Atomic Energy Authority; the National Academy of Sciences of Ukraine, and State Fund for Fundamental Researches, Ukraine; the Science and Technology Facilities Council, U.K.; the US Department of Energy, and the US National Science Foundation.

†: Deceased
1: Also at Vienna University of Technology, Vienna, Austria
2: Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland
3: Also at State Key Laboratory of Nuclear Physics and Technology, Peking University, Beijing, China
4: Also at Institut Pluridisciplinaire Hubert Curien, Université de Strasbourg, Université de Haute Alsace Mulhouse, CNRS/IN2P3, Strasbourg, France
5: Also at National Institute of Chemical Physics and Biophysics, Tallinn, Estonia
6: Also at Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia
7: Also at Universidade Estadual de Campinas, Campinas, Brazil
8: Also at Centre National de la Recherche Scientifique (CNRS) - IN2P3, Paris, France
9: Also at Laboratoire Leprince-Ringuet, Ecole Polytechnique, IN2P3-CNRS, Palaiseau, France
10: Also at Joint Institute for Nuclear Research, Dubna, Russia
11: Also at Helwan University, Cairo, Egypt
12: Now at Zewail City of Science and Technology, Zewail, Egypt
13: Also at Beni-Suef University, Bani Sweif, Egypt
14: Now at British University in Egypt, Cairo, Egypt
15: Now at Ain Shams University, Cairo, Egypt
16: Also at Université de Haute Alsace, Mulhouse, France
17: Also at Tbilisi State University, Tbilisi, Georgia
18: Also at RWTH Aachen University, III. Physikalisches Institut A, Aachen, Germany
19: Also at Indian Institute of Science Education and Research, Bhopal, India
20: Also at University of Hamburg, Hamburg, Germany
21: Also at Brandenburg University of Technology, Cottbus, Germany
22: Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary
23: Also at Eötvös Loránd University, Budapest, Hungary
24: Also at University of Debrecen, Debrecen, Hungary
25: Also at Wigner Research Centre for Physics, Budapest, Hungary
26: Also at University of Visva-Bharati, Santiniketan, India
27: Now at King Abdulaziz University, Jeddah, Saudi Arabia
28: Also at University of Ruhuna, Matara, Sri Lanka
29: Also at Isfahan University of Technology, Isfahan, Iran
30: Also at University of Tehran, Department of Engineering Science, Tehran, Iran
31: Also at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran
32: Also at Università degli Studi di Siena, Siena, Italy
33: Also at Purdue University, West Lafayette, U.S.A.
34: Also at International Islamic University of Malaysia, Kuala Lumpur, Malaysia
35: Also at Malaysian Nuclear Agency, MOSTI, Kajang, Malaysia
36: Also at Consejo Nacional de Ciencia y Tecnología, Mexico city, Mexico
37: Also at Warsaw University of Technology, Institute of Electronic Systems, Warsaw, Poland
38: Also at Institute for Nuclear Research, Moscow, Russia
39: Now at National Research Nuclear University 'Moscow Engineering Physics Institute' (MEPhI), Moscow, Russia
40: Also at St. Petersburg State Polytechnical University, St. Petersburg, Russia
41: Also at California Institute of Technology, Pasadena, U.S.A.
42: Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia
43: Also at INFN Sezione di Roma; Università di Roma, Roma, Italy
44: Also at National Technical University of Athens, Athens, Greece
45: Also at Scuola Normale e Sezione dell’INFN, Pisa, Italy
46: Also at University of Athens, Athens, Greece
47: Also at Institute for Theoretical and Experimental Physics, Moscow, Russia
48: Also at Albert Einstein Center for Fundamental Physics, Bern, Switzerland
49: Also at Gaziosmanpasa University, Tokat, Turkey
50: Also at Adiyaman University, Adiyaman, Turkey
51: Also at Mersin University, Mersin, Turkey
52: Also at Cag University, Mersin, Turkey
53: Also at Piri Reis University, Istanbul, Turkey
54: Also at Ozyegin University, Istanbul, Turkey
55: Also at Izmir Institute of Technology, Izmir, Turkey
56: Also at Marmara University, Istanbul, Turkey
57: Also at Kafkas University, Kars, Turkey
58: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey
59: Also at Yildiz Technical University, Istanbul, Turkey
60: Also at Hacettepe University, Ankara, Turkey
61: Also at Rutherford Appleton Laboratory, Didcot, United Kingdom
62: Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
63: Also at Instituto de Astrofísica de Canarias, La Laguna, Spain
64: Also at Utah Valley University, Orem, U.S.A.
65: Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia
66: Also at Facoltà Ingegneria, Università di Roma, Roma, Italy
67: Also at Argonne National Laboratory, Argonne, U.S.A.
68: Also at Erzincan University, Erzincan, Turkey
69: Also at Texas A&M University at Qatar, Doha, Qatar
70: Also at Kyungpook National University, Daegu, Korea
